6 anti-patterns and how to fix them

Decision Framework
Strategy selection by use case

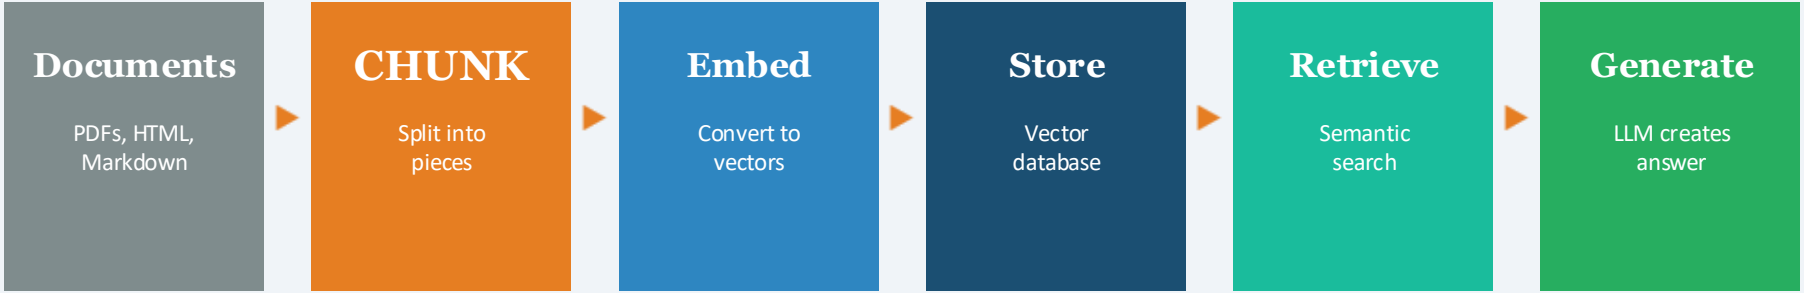
Production Checklist
Ship-ready verification steps

01

Why Chunking Matters

The chunk is your fundamental unit of retrieval.
Get it wrong and everything downstream suffers.

Where Chunking Fits in the RAG Pipeline



The chunk is your unit of retrieval. Whatever you defined as a chunk determines the quality ceiling of your entire RAG pipeline. Not the embedding model. Not the LLM. The chunks.

The Chunk Quality Principle

- Independently meaningful — readable without surrounding context
- Semantically coherent — about one topic, not two glued together
- Right-sized for queries — matches the granularity users will ask about

The Fundamental Tension: Chunk Size Tradeoffs

Dimension	Too Small (128 tok)	Too Large (1024+ tok)	Sweet Spot (~512 tok)
Precision	High match, no context	Noisy, diluted embedding	Precise match + context
Context	Fragment lacks meaning	Context overwhelms signal	Self-contained unit
Retrieval	Exact sentence found	Relevant content buried	Right info surfaces
Cost	Many embeddings stored	Fewer, cheaper	Balanced
LLM Output	Partial answers, hallucination	Noise confuses model	Grounded, accurate
Embedding	Sparse vector, little signal	Over-compressed semantics	Clean topic representation

There is no universal best chunk size. The optimal size depends on document types, query patterns, embedding model sweet spot, and business requirements.

Chunk Size Quick Reference

Size	Token Range	Best Query Type	Best Document Type	Embedding Model Notes
Small	128–256	Factoid: "What year?", "Who is?"	FAQs, contracts, definitions	all-MiniLM-L6-v2 sweet spot
Medium	256–512	Balanced: "Explain X", "How does?"	Reports, articles, docs	Most models' optimal range
Large	512–1024	Complex: "Compare X and Y"	Narratives, analysis	text-embedding-3-large
Very Large	1024–2048	Synthesis questions	Books, research papers	Use with parent-child pattern

Character-Based vs Token-Based Counting

Always prefer token-based in production. Character-based is simpler but unpredictable — a 2000-char chunk might be 400 or 600 tokens. Token-based aligns with how embedding models process text (token limits, not char limits). Use tiktoken (OpenAI), HuggingFace tokenizers, or spaCy.

02

Rule-Based Chunking

Fast, predictable, and cheap.
The foundation every pipeline needs.

Strategy 1: Fixed-Size Chunking

How It Works

Cut text every N characters or N tokens. No analysis, no NLP, no cost beyond string slicing.

```
Document:
"The capital of France is Paris. Paris
 is known for the Eiffel Tower."

Chunk size = 50 chars:
Chunk 1: "The capital of France is Paris. Paris is kno"
Chunk 2: "wn for the Eiffel Tower."
```

⚠ **Broken mid-word! Neither chunk is independently meaningful.**

Complexity: Very Low	Cost: Very Low	Quality: Low

```
Python: text[i:i+chunk_size]
LangChain: CharacterTextSplitter
```

When to Use

- Rapid prototyping — working pipeline in minutes
- Baseline benchmarking — control group for testing
- Highly uniform text (product descriptions, logs)

When NOT to Use

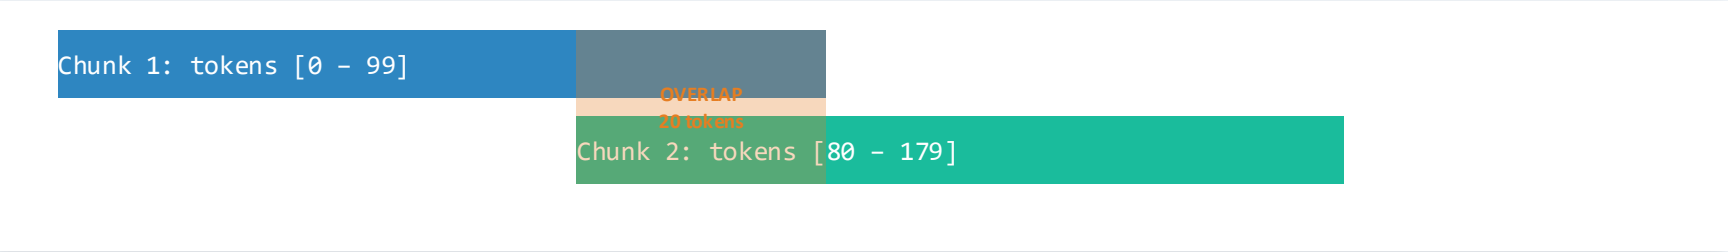
- Structured documents (headings, sections, tables)
- Multi-topic documents (reports, books, papers)
- Any production system (almost always worth upgrading)

Common Pitfall

Fixed-size chunking is deceptively convenient. Many teams ship it because it worked in the demo, then spend weeks debugging quality issues that all trace back to broken chunks.

Strategy 2: Sliding Window with Overlap

Overlap is a modifier applied on top of fixed-size chunking. Adjacent chunks share text.



Overlap %	Pros	Cons	Best For
0%	No redundancy, minimal storage	Boundary info loss	Very uniform text
10%	Light safety net for boundaries	May still miss context	General default
20%	Good boundary coverage	Noticeable storage increase	Flowing narratives
30%+	Maximum boundary safety	Heavy duplication, retrieval pollution	Rarely justified

⚠ **Dedup Problem: With 20% overlap and top-5 retrieval, you may get 3 chunks that are 80% identical. Wastes top-K budget. Use a reranker or dedup step.**

Strategy 3: Recursive Character Text Splitting

The most widely used chunking strategy in production — LangChain's default

P1	\n\n	Paragraph breaks	Best
P2	\n	Line breaks	Good
P3	.	Sentence ends	OK
P4	" "	Word boundaries	Poor
P5	""	Char split	Last Resort

The Algorithm

1. Try highest-priority separator
2. If chunks within size limit → done
3. If any chunk too big → recurse with next separator
4. Degrades gracefully down the list

Production Recommendation

- 512 tokens chunk size
- 50-token overlap
- Measure retrieval quality
- Upgrade ONLY with evidence

This is your baseline. Many production systems never need more.

Strategy 4: Sentence-Level Chunking

How It Works

Parse text into sentences using NLP (spaCy, NLTK), group N sentences per chunk. Every chunk = complete, grammatically valid sentences.

```
import spacy
nlp = spacy.load("en_core_web_sm")
sents = [s.text for s in nlp(text).sents]
# Group every 5 sentences into a chunk
```

✓ Pros

Never breaks mid-sentence. Clean embeddings. Works well with sentence window retrieval pattern.

✗ Cons

Doesn’t resolve coreference. "This is important" — what is "this"? Requires NLP dependency. Variable chunk sizes.

Sentence Window Retrieval (LlamaIndex SentenceWindowNodeParser)

Retrieve the matching sentence for precision, return sentence + N surrounding for LLM context. Best of both worlds.

Strategy 5: Document-Structure-Aware Chunking

Use the structure the author already created — headings, sections, HTML tags, AST nodes

Doc Type	Structural Elements	Chunking Approach	Tools
Markdown	# Headings, ## Sub	Split at heading boundaries	LangChain MarkdownHeaderTextSplitter
HTML	<h1>, <section>,	Split at tag boundaries	LangChain HTMLHeaderTextSplitter
PDF	Detected headings, sections	Split at section boundaries	unstructured.io, docling, PyMuPDF
Code	Functions, classes, modules	Split at AST boundaries	tree-sitter, custom parsers
LaTeX	\section, \subsection	Split at LaTeX commands	Custom regex parsers

✓ Strengths

- Leverages human-created organization
- Section boundaries = topic boundaries
- Headings become metadata for filtering
- No NLP or embedding cost

✗ Limitations

- Not all docs have structure (wall-of-text PDFs)
- Sections may be very long (need sub-split)
- Sections may be very short (need merging)
- PDF structure detection is imperfect

03

Semantic Chunking

Using embeddings and LLMs to understand meaning and make intelligent boundary decisions.

Strategy 6: Embedding-Based Semantic Chunking

Pioneered by Greg Kamradt — detect topic shifts using embedding similarity

The Algorithm (4 Steps)

Step 1	Step 2	Step 3	Step 4
Split into sentences	**Embed each sentence**	**Compute similarity**	**Detect breakpoints**
Standard NLP sentence detection	One embedding API call per sentence	Cosine sim between consecutive pairs	Where similarity drops = topic shift

"Paris is the capital"	↔ "Famous for Eiffel Tower"	0.89	Same topic
"Famous for Eiffel Tower"	↔ "Tower attracts millions"	0.91	Same topic
" Python 3.12 released "	↔ "Python 3.12 released"	0.23	TOPIC SHIFT → split here

Breakpoint Methods: Percentile | Std Deviation | Gradient | Clustering

Semantic Chunking: Tradeoffs & Cost Analysis

✓ Strengths

- Chunks are semantically coherent — one topic each
- Clean topic representation in embeddings
- Retrieval jumps for topic-diverse docs
- Adaptive chunk sizes based on content
- LlamaIndex SemanticSplitterNodeParser available

✗ Limitations

- Requires embedding every individual sentence first
- 100K sentences = 100K embedding API calls
- Sensitive to threshold/percentile tuning
- Benefits found inconsistent (Oct 2024 paper)
- Locally greedy, not globally optimal

⚠ Cost Reality Check

"Is Semantic Chunking Worth the Computational Cost?" (arXiv:2410.13070, Oct 2024) found benefits inconsistent and often insufficient to justify the expense vs recursive splitting.

Always A/B test with YOUR queries and documents before committing to semantic chunking in production.

Strategy 7: Proposition-Based Chunking

Decompose text into atomic, self-contained facts using an LLM

```
INPUT:
"Paris, the capital of France,
was founded in the 3rd century
BC and has a population of
2.1 million."
```

→

```
PROPOSITIONS:
1. "Paris is the capital of France"
2. "Paris was founded in 3rd century BC"
3. "Paris has a population of 2.1 million"
```

✓ When to Use	✗ When NOT to Use
High-value, small KBs (legal, medical)	Large corpora (cost prohibitive)
FAQ / knowledge base construction	Docs requiring narrative context
Factoid-style queries for specific data	Complex multi-hop questions
Compliance/audit where precision is critical	Rapidly changing content needing re-index

Strategy 8: Agentic / LLM-Based Chunking

The most sophisticated approach: LLM reads text and decides chunk boundaries

Boundary Detection

LLM decides WHERE to split.
One call per document section.

Cost: Medium

Quality: High

```
"Break into self-contained chunks, one topic each."
```

Proposition Extraction

Decompose into atomic facts.
One call per passage.

Cost: High

Quality: Very High

```
"Extract all standalone facts from this passage."
```

Full Agentic

Chunks + metadata + validation.
Multiple LLM calls per doc.

Cost: Very High

Quality: Highest

```
"Chunk + add title/summary metadata + validate."
```

⚠ Cost-Quality Tradeoff: Agentic on 1M documents = thousands in LLM costs. Reserve for high-value, smaller corpora (legal, medical, compliance) where retrieval quality justifies expense.

04

Advanced Patterns

Parent-child indexing, contextual retrieval,
and late chunking — the cutting edge.

Pattern 1: Parent-Child (Hierarchical) Chunking

Index small chunks for precise retrieval. Return the larger parent for LLM context.

PARENT CHUNK (2000 tokens) — Full section: France, Paris, Eiffel Tower history

Child 1

France in
Western Europe

Child 2

Paris known for
Eiffel, Louvre

Child 3 ★

Eiffel Tower 1889
by Gustave Eiffel

Child 4

Tower 330m
tallest until 1930

`Query: "Who designed the Eiffel Tower?"` → Child 3 matches → **PARENT returned to LLM**

Implementation	How It Works	Tool
Sentence Window	Retrieve sentence, return + N surrounding	LlamaIndex SentenceWindowNodeParser
Auto-Merging	If enough children match, merge up to parent	LlamaIndex HierarchicalNodeParser
Multi-Level	Doc > Section > Paragraph > Sentence	Custom implementation

Pattern 2: Contextual Chunking (Anthropic, Sept 2024)

BEFORE: Raw Chunk

```
"Revenue increased by 23% YoY, driven by expansion
into Asia."
```

⚠ **Which company? What year? What division?**

AFTER: Contextualized

[Context: Acme Corp 2024 Annual Report, Q4.]
"Revenue increased by 23% YoY..."

Configuration	Failure Rate	Improvement
Traditional RAG (baseline)	5.7%	—
Contextual Embeddings only	3.7%	35% reduction
Contextual + BM25 hybrid	2.9%	49% reduction
Contextual + BM25 + Reranking	1.9%	67% reduction

Key Optimization: Use prompt caching — document processed once, cached for all chunk calls. Use cheap models (Haiku, 4o-mini) for context generation.

Pattern 3: Late Chunking (Jina AI, 2024)

Embed the entire document first, THEN chunk the embeddings

Traditional: Chunk → Embed

Each chunk embedded in isolation.
Pronouns like "it" and "this" lose referent.

✗ "Its 3.85M inhabitants..." + query "Berlin population" → LOW similarity (no Berlin mention in chunk)

Late: Embed → Chunk

Full doc through long-context transformer.
Every token encodes entire doc context.

✓ Same chunk now contextually enriched → HIGH similarity with "Berlin population"

Dimension	Late Chunking (Jina)	Contextual (Anthropic)
Approach	Embed first, chunk embeddings	Chunk first, prepend LLM context
Extra Cost	None — no LLM calls	1 LLM call per chunk
Context Source	Transformer attention mechanism	Explicit LLM description
Model Required	Long-context embed model (8K+)	Any embed model + LLM
Best For	Large corpora, cost-sensitive	High-value, precision-critical

05

Special Content Handling

Tables, code, images, and conversations each require dedicated strategies.

Handling Tables in Documents

The Problem: A table split mid-row loses header-data relationships. Chunk 1 gets headers, Chunk 2 gets orphaned data rows.

```
Chunk 2: "2023 | $65M | $8M | 2024 | $82M | $12M" ← No headers! $82M means nothing.
```

Strategy	How It Works	Pros	Cons
Keep whole	Entire table = one chunk	All relationships preserved	Large tables exceed limits
Serialize to MD	Convert to Markdown format	Better embedding quality	Still may be large
LLM Summarize	Generate NL summary	Excellent for semantic search	Loses exact numbers
Row + headers	Each row + headers prepended	Precise per-row retrieval	Many small chunks
Multi-rep	Raw table + summary stored	Covers exact + semantic	Double storage cost

Code, Multimodal & Conversational Data

Code Files

- AST-based: split by function/class
- Prepend class name & imports to each
- Pair code with docstrings
- Use tree-sitter for parsing
- Never break a function in half

Images & Charts

- Vision model → text desc → embed
- Multimodal embeddings (CLIP)
- Hybrid: text retrieve + image to LLM
- Chart/diagram captioning
- Store image + desc as separate chunks

Conversations & QA

- Keep Q&A pairs together always
- Never split question from answer
- Long convos: chunk by topic/thread
- Include ticket metadata
- Resolution paragraph as chunk

06

Metadata Enrichment

A chunk without metadata is a page torn from a book with no title.

Essential Metadata Fields for RAG Chunks

Field	Purpose	Example
source_document	Origin for citation + filtering	"2024_Annual_Report.pdf"
page_number	Page-level reference	47
section_hierarchy	Situate within doc structure	"Ch 3 > Finance > Revenue"
chunk_position	Know if context before/after	"middle" (3 of 7 in section)
document_date	Enable temporal filtering	"2024-03-15"
content_type	Distinguish text/table/code	"table"
entities	Pre-extracted key entities	["Acme Corp", "Q3 2024"]

Filtered Retrieval

"Find revenue from 2024 report" — filter by doc before vector search

Source Attribution

LLM cites: "Per page 47 of Annual Report..." Builds trust.

Deduplication

Position metadata identifies overlap, preventing redundant results.

07

Evaluation Framework

Without measurement, you are guessing.
With evaluation, you have evidence.

Retrieval & End-to-End RAG Metrics

Retrieval Metrics

Recall@K	Did we find the right chunks?
Precision@K	Did we avoid irrelevant chunks?
MRR	How quickly does right answer appear?
nDCG@10	Are best chunks ranked highest?

End-to-End RAG Metrics

Faithfulness	Answer supported by chunks?
Answer Relevancy	Addresses the question?
Context Relevancy	Retrieved chunks relevant?
Answer Correctness	Matches ground truth?

Practical 4-Step Evaluation

Step 1

Create 50–100 Q&A pairs from your docs. Note which section answers.

Step 2

Run with different chunking strategies, same model & LLM.

Step 3

Measure retrieval + end-to-end (right chunks? correct answers?).

Step 4

RAGAS, DeepEval, or manual spot-checking to automate.

The Most Underrated Evaluation Method

Visual Inspection: Just LOOK at 20 random chunks

Ask yourself: Does this chunk make sense in isolation? Would a human understand it without context?

What to Look For:

- ✅ Does the chunk answer at least one plausible user question?
- ✅ Is the chunk about one topic, or is it a frankenchunk?
- ✅ Are references resolved? (no orphan "this", "above", "Table 3")
- ❌ Is any table split across chunks? (check for orphaned rows)
- ❌ Are there chunks that are just headers with no content?
- ❌ Are identical or near-identical chunks appearing?

08

Common Failure Modes

Understanding what goes wrong is as important as understanding what works.

6 Failure Modes That Break RAG Pipelines

The Cliffhanger

Chunk ends: "The solution is..."

✓ **Fix:** Sentence-aware splitting or overlap

The Frankenchunk

End of Topic A + start of Topic B

✓ **Fix:** Structure-aware or semantic chunking

The Orphan Reference

"As shown in Table 3.2 above..."

✓ **Fix:** Contextual chunking or parent-child

The Table Massacre

Table split across 3 chunks

✓ **Fix:** Dedicated table detection + handling

The Duplicate Flood

Top-5 returns 80% identical chunks

✓ **Fix:** Reduce overlap, add reranker/dedup

The Lost Needle

Critical fact buried in 1024-tok chunk

✓ **Fix:** Smaller chunks or propositions

09

Decision Framework

Start simple. Measure rigorously.
Add complexity only when it demonstrably helps.

The 4-Step Decision Process

1 BASELINE

Recursive splitting
512 tokens, 50 overlap
Measure quality

2 DIAGNOSE

Look at failures
Identify failure mode
Use failure table

3 TARGET

Apply specific fix
for observed failure
Don’t upgrade all

4 MEASURE

Measure on eval set
If helps → keep
If not → revert

Strategy Selection by Use Case

Use Case	Primary Strategy	Enhancement
General knowledge base	Recursive (512 tok, 50 overlap)	Metadata enrichment
Financial / legal docs	Structure-aware + contextual	Parent-child + table handling
FAQ / Support content	Q&A pairs as chunks	Metadata tagging by category
Code repositories	AST-based chunking	Import/class context prepended
Research papers	Section-based splitting	Contextual chunking for refs
Mixed document types	Type-detection router	Strategy per type pipeline
Large-scale, cost-sensitive	Recursive + late chunking	BM25 hybrid search
High-value, precision	Contextual + reranking	Propositions for key sections

Master Strategy Comparison

Strategy	Complexity	Cost	Quality	Best For
Fixed-Size	Very Low	Very Low	Low	Prototyping, baselines
Recursive Character	Low	Low	Med-High	General production
Sentence-Level	Low	Low	Medium	Clean text + NLP
Document Structure	Medium	Low	High	Well-structured docs
Semantic (Embedding)	Medium	Medium	High	Topic-diverse docs
Proposition	High	High	Very High	Legal, medical
Agentic (LLM)	Very High	Very High	Highest	Small high-value corpora
Parent-Child	Medium	Low	High	Any production system
Contextual (Anthropic)	Medium	Med-High	Very High	Enterprise documents
Late Chunking (Jina)	Medium	Low	High	Large corpora, cost

10

Production Checklist

Before shipping your RAG pipeline,
verify each of these items.

Production Chunking Checklist

Ingestion Pipeline

- ☐ Document type detection + routing
- ☐ Structure extraction (headings, tables)
- ☐ Table detection + dedicated strategy
- ☐ Chunk size validation (50–model limit)
- ☐ Overlap consistency verified

Metadata

- ☐ Source document ID on every chunk
- ☐ Page + section hierarchy attached
- ☐ Content type tagged (text/table/code)
- ☐ Temporal metadata for date filtering
- ☐ Entity extraction where applicable

Quality Assurance

- ☐ 50+ Q&A evaluation pairs created
- ☐ 20+ random chunks manually reviewed
- ☐ Each failure mode tested for
- ☐ A/B comparison of 2+ strategies
- ☐ Reranker tested on results

Operational

- ☐ Incremental update support built
- ☐ Cost per document monitored
- ☐ Near-duplicate dedup at retrieval
- ☐ Chunking decisions logged
- ☐ Quality degradation alerting

Key Takeaway

The best RAG systems don’t use one chunking strategy.

They use a pipeline that routes documents to different strategies based on content type, applies metadata enrichment, uses parent-child indexing, and evaluates results continuously.

Start simple. Measure rigorously. Add complexity only when it helps.
