1. Why Chunking is the Most Critical Step in RAG

In Retrieval-Augmented Generation (RAG), the **chunk is your fundamental unit of retrieval**. When a user asks a question, your system does not return documents or pages. It returns chunks. Whatever you defined as a chunk determines the quality ceiling of your entire RAG pipeline.

Consider a 200-page annual report. A user asks about Q3 revenue growth. You cannot send the entire document to the LLM; it would be expensive, slow, and the model would struggle to locate the relevant needle in that haystack. Instead, you break the document into smaller pieces, embed those pieces into vectors, and retrieve only the ones most semantically similar to the query.

This seemingly simple step of breaking documents into chunks is where **the majority of RAG quality issues originate**. Not in the embedding model. Not in the LLM. Not in the vector database. In the chunks themselves.

1.1 The Fundamental Tension

Every chunking decision involves navigating three competing forces:

Dimension	Too Small	Too Large	Sweet Spot
Precision	High match but no context	Noisy, diluted embedding	Precise match with sufficient context
Context	Fragment lacks meaning	Context overwhelms signal	Self-contained, meaningful unit
Retrieval	Exact sentence found	Relevant content buried in noise	Right information surfaces reliably
Cost	Many embeddings, more storage	Fewer embeddings, cheaper	Balanced storage and quality
LLM Output	Partial answers, hallucination	Noise confuses the model	Grounded, accurate answers

1.2 The Chunk Quality Principle

> **The Golden Rule of Chunking**
>
> A good chunk should be independently meaningful. If a human reads the chunk in isolation, without any surrounding context, they should understand what it is about and find it useful for answering a question on that topic. If they cannot, the chunk will fail at retrieval.

Before diving into strategies, understand that chunking is *not* a one-size-fits-all problem. The optimal strategy depends on your document types, query patterns, embedding model, and

business requirements. The strategies in this guide are presented in order of increasing sophistication, from simple baselines to cutting-edge approaches.

2. Category I: Rule-Based Chunking Strategies

Rule-based strategies use deterministic rules (character counts, delimiters, syntax) to decide chunk boundaries. They are fast, predictable, cheap, and easy to debug. They form the baseline against which all advanced methods should be compared.

2.1 Fixed-Size Chunking

The simplest possible approach. Text is divided into chunks of exactly **N characters** or **N tokens**, with no regard for content, sentence boundaries, or semantic coherence.

How It Works

The algorithm walks through the text and cuts at every Nth position. That is all there is to it. No analysis, no intelligence, no cost beyond string slicing.

```
Document: "The capital of France is Paris. Paris is known for the Eiffel
          Tower. The tower was built in 1889."

Chunk size: 50 characters

Chunk 1: "The capital of France is Paris. Paris is known fo"
Chunk 2: "r the Eiffel Tower. The tower was built in 1889."
```

Notice how `"known fo"` and `"r the Eiffel Tower"` are split mid-word. The embedding for Chunk 1 encodes a broken sentence. If someone searches for what Paris is known for, neither chunk provides a complete answer.

Character-Based vs Token-Based

Character-based counting is simpler but less predictable. A 2000-character chunk might be 400 tokens or 600 tokens depending on vocabulary complexity. Token-based counting aligns with how embedding models actually process text, since they have token limits, not character limits. Always prefer token-based counting in production.

When to Use

- **Rapid prototyping:** When you need a working pipeline in minutes to test the end-to-end flow.

- **Uniform text:** When documents are highly homogeneous (e.g., product descriptions of similar length).
- **Baseline benchmarking:** As the control group against which you measure all other strategies.

When NOT to Use

- **Documents with structure:** Any document with headings, sections, tables, or code.
- **Mixed-topic documents:** Reports, books, or papers that cover multiple subjects.
- **Production systems:** Almost always worth upgrading to at least recursive splitting.

> **Common Pitfall**
> Fixed-size chunking is deceptively convenient. Many teams ship it to production because it worked in the demo, then spend weeks debugging retrieval quality issues that trace back to broken chunks.

2.2 Sliding Window with Overlap

Overlap is not a chunking strategy in itself but a **modifier** applied on top of fixed-size chunking. Instead of cutting cleanly at boundaries, adjacent chunks share a portion of their text.

```
Chunk size: 100 tokens, Overlap: 20 tokens

Chunk 1: tokens [0 - 99]
Chunk 2: tokens [80 - 179]     (shares tokens 80-99 with Chunk 1)
Chunk 3: tokens [160 - 259]    (shares tokens 160-179 with Chunk 2)
```

The overlap ensures that if a critical sentence falls right at a boundary, it appears in full in at least one chunk. This is a pragmatic fix for the boundary problem of fixed-size chunking.

Overlap Size Tradeoffs

Overlap %	Pros	Cons	Best For
0%	No redundancy, minimal storage	Boundary information loss	Very uniform, simple text
10%	Light safety net	May still miss critical context	General purpose default
20%	Good boundary coverage	Noticeable storage increase	Documents with flowing narrative
30%+	Maximum boundary safety	Heavy duplication, retrieval pollution	Rarely justified

> **The Deduplication Problem**
> With 20% overlap and top-5 retrieval, you may get 2 or 3 chunks that are 80% identical. This wastes your top-K budget on redundant content. You need a deduplication step after retrieval, or you should use a reranker that naturally penalizes near-duplicates.

2.3 Recursive Character Text Splitting

This is LangChain's default and the **most widely used chunking strategy in production**. The core idea is elegant: try to split at natural document boundaries, in a priority order, degrading gracefully when needed.

The Algorithm

The splitter attempts to divide text using a hierarchy of separators, trying the most respectful boundary first:

Priority	Separator	What It Preserves	Fallback Behavior
1 (Best)	\n\n (double newline)	Paragraph boundaries	Keeps paragraphs intact
2	\n (single newline)	Line breaks	Keeps lines intact
3	. (period + space)	Sentence boundaries	Keeps sentences intact
4	" " (space)	Word boundaries	Keeps words intact
5 (Worst)	"" (empty string)	Nothing	Splits mid-character

For each piece of text, the algorithm tries the highest-priority separator first. If the resulting chunks are within the size limit, it stops. If any chunk is still too large, it recurses with the next separator. This means paragraphs stay together when possible, sentences are preserved when paragraphs are too big, and words are preserved when sentences are too long.

Why This Works Well

- It respects the document's natural structure without requiring any NLP tools.
- Degradation is graceful: you only break finer boundaries when absolutely necessary.
- It is deterministic, fast, and produces predictable output.
- Combined with overlap, it provides a solid baseline that many production systems never need to exceed.

Limitations

It is purely syntactic. Two paragraphs about completely different topics that happen to be adjacent will stay together if they fit within the chunk size. Two paragraphs about the same topic that span a chunk boundary will be split apart. It has no understanding of meaning.

> **Production Recommendation**
> Recursive character splitting with 512 tokens and 50-token overlap is the strongest baseline for most use cases. Start here, measure retrieval quality, and only upgrade to more complex strategies when you have evidence they are needed.

2.4 Sentence-Level Chunking

Instead of counting characters, this approach first **properly parses the text into sentences** using an NLP library (spaCy, NLTK, or similar), then groups N sentences into each chunk.

```
import spacy
nlp = spacy.load("en_core_web_sm")

doc = nlp(text)
sentences = [sent.text for sent in doc.sents]

# Group every 5 sentences into a chunk
chunks = []
for i in range(0, len(sentences), 5):
    chunk = " ".join(sentences[i:i+5])
    chunks.append(chunk)
```

Key advantage: You never break mid-sentence. Every chunk contains complete, grammatically valid sentences. Embeddings are cleaner because they encode complete thoughts.

Key limitation: Not all sentences are self-contained. "This is critically important." has no meaning without the preceding sentence explaining what "this" refers to. Sentence-level chunking does not resolve coreference.

Sentence Window Retrieval

A powerful extension: when you retrieve a chunk of 3 sentences, return those 3 sentences plus N sentences before and after. This gives the LLM more surrounding context. LlamaIndex implements this as SentenceWindowNodeParser. You get precision from small retrieval units with context from the expanded window.

2.5 Document-Structure-Aware Chunking

Many documents have explicit structure: headings, subheadings, sections. **Why not use the structure the author already created?**

By Document Type

Document Type	Structural Elements	Chunking Approach	Tools
Markdown	# Headings, ## Subheadings	Split at heading boundaries	LangChain MarkdownHeaderTextSplitter
HTML	<h1>, <h2>, , <section>	Split at tag boundaries	LangChain HTMLHeaderTextSplitter
PDF	Detected headings, sections	Split at section boundaries	unstructured.io, docling, PyMuPDF
Code	Functions, classes, modules	Split at AST boundaries	tree-sitter, custom parsers
LaTeX	\section, \subsection	Split at LaTeX commands	Custom parsers

Strengths

The document's author already thought about how to organize the information. Section boundaries are natural topic boundaries. You are leveraging human judgment that is already baked into the document.

Weaknesses

- Not all documents have good structure. A wall-of-text PDF with no headings gives you nothing to work with.
- Sections may be very long (requiring further sub-splitting) or very short (requiring merging of adjacent small sections).
- PDF structure detection is imperfect. Tools like unstructured.io and docling have improved dramatically, but errors still occur.

> **Hybrid Approach**
> In practice, the best results come from using structure-aware splitting as the first pass, then applying recursive or semantic splitting within any sections that exceed the chunk size limit. This gives you the benefits of both approaches.

3. Category II: Semantic Chunking Strategies

Semantic strategies use embeddings or language models to understand the meaning of text and make intelligent decisions about where to place chunk boundaries. They are more expensive but produce higher-quality chunks.

3.1 Embedding-Based Semantic Chunking

Pioneered by **Greg Kamradt** and now widely adopted, this approach uses embedding similarity to detect topic shifts and place boundaries at semantically meaningful points.

The Algorithm

Step 1: Split the document into individual sentences.

Step 2: Create embeddings for each sentence (or groups of sentences using a sliding buffer).

Step 3: Compute the cosine similarity between each consecutive pair of sentence embeddings.

Step 4: Where the similarity drops sharply, insert a chunk boundary. This drop indicates a topic shift.

```
Sentence 1: "Paris is the capital of France"        → embedding_1
Sentence 2: "It is famous for the Eiffel Tower"     → embedding_2
Sentence 3: "The tower attracts millions yearly"    → embedding_3
Sentence 4: "Python 3.12 introduced new features"  → embedding_4

Similarity(1,2) = 0.89  ← High, same topic
Similarity(2,3) = 0.91  ← High, same topic
Similarity(3,4) = 0.23  ← DROP! Topic changed!

→ Chunk 1: Sentences 1-3  (Paris / Eiffel Tower)
→ Chunk 2: Sentence 4+   (Python programming)
```

Breakpoint Detection Methods

Method	How It Works	Pros	Cons
Percentile	Split where similarity is below Nth percentile (e.g., 25th)	Simple to implement	Sensitive to threshold choice
Standard Deviation	Split where similarity is > X std deviations below mean	Statistically grounded	Assumes normal distribution
Gradient	Split at the steepest drops in similarity	Detects sharpest topic changes	May miss gradual shifts

Method	How It Works	Pros	Cons
Clustering	Group sentences via clustering algorithms	Captures global patterns	Non-sequential chunks possible

Cost Considerations

Semantic chunking requires embedding **every individual sentence** before you even produce your final chunks. For a corpus with 100,000 sentences, that is 100,000 embedding API calls just for the chunking step. A research paper from October 2024 titled "Is Semantic Chunking Worth the Computational Cost?" found that the benefits are inconsistent and sometimes insufficient to justify the expense, particularly for simpler document types.

> **Evaluate Before Adopting**
> Semantic chunking sounds appealing in theory but may not significantly outperform recursive splitting in practice for your specific use case. Always run A/B tests with your actual queries and documents before committing to the higher cost.

3.2 Proposition-Based Chunking

Instead of splitting text into paragraphs or sentences, this approach uses an LLM to decompose text into **atomic facts or propositions**. Each proposition is a standalone, self-contained statement.

```
Input: "Paris, the capital of France, was founded in the 3rd
        century BC and has a population of 2.1 million."

Propositions:
  1. "Paris is the capital of France"
  2. "Paris was founded in the 3rd century BC"
  3. "Paris has a population of 2.1 million"
```

Each proposition is a clean, precise retrieval target. If someone asks "When was Paris founded?", proposition 2 is a near-perfect match. There is no dilution from unrelated information.

When to Use

- High-value, smaller knowledge bases where retrieval precision is critical (legal, medical, compliance).
- FAQ and knowledge base construction where atomic facts serve as natural retrieval units.

- When your queries are predominantly factoid-style questions seeking specific data points.

When NOT to Use

- Large corpora where LLM processing cost per chunk is prohibitive.
- Documents requiring narrative context (the decomposition loses the "flow" of reasoning).
- When queries are complex, multi-hop questions that need broader context than a single fact.

3.3 Agentic / LLM-Based Chunking

The most sophisticated rule-free approach: use an LLM to **read the text and decide chunk boundaries** based on its understanding of content, topic, and structure.

You prompt an LLM with instructions such as: "Break this document into self-contained chunks where each chunk covers a single topic or concept. Each chunk should be understandable on its own without requiring context from other chunks."

The LLM reads the text, understands meaning, resolves references, detects topic shifts, and produces intelligent boundaries. It can also enrich each chunk with a summary or title.

Comparison of LLM-Driven Approaches

Approach	What the LLM Does	Cost	Quality
Boundary Detection	Decides WHERE to split	1 LLM call per document section	High
Proposition Extraction	Decomposes text into atomic facts	1 LLM call per passage	Very High for factoid retrieval
Full Agentic	Decides chunks, generates metadata, validates	Multiple LLM calls per document	Highest

Cost-Quality Tradeoff

Agentic chunking on a corpus of 1 million documents could cost thousands of dollars in LLM API calls. Reserve this for high-value, smaller corpora where the cost is justified by the retrieval quality improvement.

4. Category III: Advanced Chunking Patterns

These patterns go beyond simple chunking strategies. They change how chunks are indexed, retrieved, or enriched to solve specific problems that no single chunking strategy can address alone.

4.1 Parent-Child (Hierarchical) Chunking

This is one of the **most important patterns in production RAG**. It elegantly solves the fundamental small-vs-large chunk dilemma by decoupling the unit of retrieval from the unit of context.

> **The Core Idea**
> Index small chunks for precise retrieval. But when a small chunk matches, return its larger parent chunk to the LLM. You get precision from small embeddings and context from the larger surrounding text.

How It Works

```
Parent (2000 tokens) - Full section about the Eiffel Tower:
  "France is a country in Western Europe. Its capital is Paris...
   The Eiffel Tower was built in 1889... designed by Gustave Eiffel...
   The tower stands 330 meters tall..."

Children (200 tokens each) - Indexed for retrieval:
  Child 1: "France is a country in Western Europe. Its capital is Paris."
  Child 2: "Paris is known for the Eiffel Tower, the Louvre, and Notre-Dame."
  Child 3: "The Eiffel Tower was built in 1889... designed by Gustave Eiffel."
  Child 4: "The tower stands 330 meters tall... tallest structure until 1930."

Query: "Who designed the Eiffel Tower?"
  → Child 3 matches perfectly (precise retrieval)
  → Parent chunk returned to LLM (full context)
```

Implementation Options

Pattern	Description	Tool Support
Sentence Window	Retrieve sentence, return sentence + N surrounding sentences	LlamaIndex SentenceWindowNodeParser
Auto-Merging	If enough children from same parent are retrieved, auto-merge to parent	LlamaIndex HierarchicalNodeParser + AutoMergingRetriever

Pattern	Description	Tool Support
Multi-Level	3+ levels: document > section > paragraph > sentence	Custom implementation

Production recommendation: Parent-child chunking should be your default for any non-trivial RAG system. The implementation overhead is minimal (store a parent_id with each child chunk) and the quality improvement is consistently significant across use cases.

4.2 Contextual Chunking (Anthropic's Approach)

Published by Anthropic in September 2024, **contextual retrieval** is one of the most impactful recent innovations in RAG. The technique addresses a fundamental flaw: chunks lose the context of the document they came from.

The Problem

```
Original chunk (from page 47 of Acme Corp's 2024 Annual Report):
  "Revenue increased by 23% year over year, driven primarily by
   expansion into the Asian market."

Problem: Which company? What year? What division? All context is lost.
```

The Solution

Before embedding each chunk, use an LLM to prepend a short contextual description that situates the chunk within its source document:

```
Contextualized chunk:
  "[Context: This chunk is from Acme Corp's 2024 Annual Report,
   specifically the Financial Performance section discussing Q4 results.
   The previous quarter's revenue was $314 million.]
   Revenue increased by 23% year over year, driven primarily by
   expansion into the Asian market."
```

The contextual prefix gets embedded along with the chunk content. Now the embedding captures not just what the chunk says, but where it fits in the bigger picture.

Results

Configuration	Retrieval Failure Rate	Improvement vs Baseline
Traditional RAG (baseline)	5.7%	—
Contextual Embeddings only	3.7%	35% reduction
Contextual Embeddings + BM25	2.9%	49% reduction
Contextual + BM25 + Reranking	1.9%	67% reduction

The Prompt

```
<document>
{{WHOLE_DOCUMENT}}
</document>

Here is the chunk we want to situate within the whole document:
<chunk>
{{CHUNK_CONTENT}}
</chunk>

Please give a short succinct context to situate this chunk within
the overall document for the purposes of improving search retrieval
of the chunk. Answer only with the succinct context and nothing else.
```

Cost Optimization

The naive approach requires one LLM call per chunk with the full document in context. With **prompt caching** (available in Claude and other APIs), the document only needs to be processed once, and subsequent chunk contextualization calls are dramatically cheaper and faster. For a 100-chunk document, you make 100 LLM calls, but 99 of them benefit from the cached document prefix.

> **When to Use Contextual Chunking**
> Contextual chunking is most valuable for enterprise document collections where chunks frequently reference information outside their boundaries: financial reports, legal contracts, technical documentation, research papers. For simple FAQ-style content where each chunk is already self-contained, the benefit is minimal.

4.3 Late Chunking (Jina AI's Approach)

Introduced by Jina AI in 2024, late chunking challenges the conventional pipeline by **reversing the order of embedding and chunking**.

Traditional Pipeline vs Late Chunking

Step	Traditional Pipeline	Late Chunking Pipeline
Step 1	Chunk the document into pieces	Embed the FULL document with a long-context model
Step 2	Embed each chunk independently	Split the resulting token embeddings into chunks
Step 3	Store chunk embeddings	Pool each chunk's token embeddings into chunk-level embeddings
Key Difference	Each chunk is embedded in isolation	Every token embedding already encodes full document context

Why It Works

In a transformer model, every token's embedding is influenced by **every other token** through the attention mechanism. When you embed the full document first, a pronoun like "it" in sentence 5 already has its embedding enriched by the entity it refers to in sentence 1. When you then split these contextually-rich token embeddings into chunks, each chunk's embedding carries information from the broader document.

```
Document: "Berlin is the capital of Germany. Its more than 3.85
           million inhabitants make it the EU's most populous city."

Traditional (chunk then embed):
  Chunk 2 embedding: "Its more than 3.85 million inhabitants..."
  → Query "Berlin population" → LOW similarity (no mention of Berlin)

Late chunking (embed then chunk):
  Chunk 2 embedding: Still references Berlin through transformer attention
  → Query "Berlin population" → HIGH similarity
```

Requirements and Limitations

- **Requires a long-context embedding model** (e.g., Jina Embeddings v2/v3 with 8192 token support).
- **Document must fit within the model's context window.** For very long documents, you still need pre-splitting.
- **The embedding model must use mean pooling** (not CLS token pooling) for late chunking to work correctly.
- **Less control over chunk boundaries** since chunking happens in token space, not semantic space.

Late Chunking vs Contextual Retrieval

Dimension	Late Chunking (Jina)	Contextual Retrieval (Anthropic)
Approach	Embed first, chunk the embeddings	Chunk first, prepend LLM-generated context
Cost	No additional LLM calls	One LLM call per chunk
Context Source	Transformer attention mechanism	Explicit LLM-generated description
Model Requirement	Long-context embedding model	Any embedding model + LLM for context
Latency	One embedding pass per document	Many LLM calls during indexing
Best For	Large corpora, cost-sensitive	High-value documents, precision-critical

5. Handling Special Content Types

Real-world documents are not just plain text. They contain tables, code, images, and conversational data. Each requires specialized handling to avoid destroying information during chunking.

5.1 Tables in Documents

Tables are the **bane of RAG pipelines**. A table split across chunks loses the relationship between headers and data:

```
| Year | Revenue | Profit |
|------|---------|--------|
| 2022 | $50M    | $5M    |
| 2023 | $65M    | $8M    |
| 2024 | $82M    | $12M   |

Naive chunking might produce:
  Chunk 1: "Year | Revenue | Profit | 2022 | $50M | $5M"
  Chunk 2: "2023 | $65M | $8M | 2024 | $82M | $12M"

Chunk 2 has data but NO headers. The embedding model cannot
associate "$82M" with "revenue" because the header is in Chunk 1.
```

Strategies for Tables

Strategy	How	Pros	Cons
Keep whole	Detect table boundaries; entire table = one chunk	Preserves all relationships	Large tables may exceed chunk limits
Serialize to Markdown	Convert to Markdown table format	Better embedding than raw cells	Still may be large
LLM Summarization	Generate natural language summary	Excellent for embedding and retrieval	Loses exact numbers sometimes
Row-level with headers	Each row becomes chunk with headers prepended	Precise per-row retrieval	Many small chunks

> **Best Practice: Multi-Representation**

> For critical tables, create multiple representations: store the raw table as one chunk (for exact data retrieval) AND an LLM-generated summary as another chunk (for semantic retrieval). This covers both exact-match and semantic search patterns.

5.2 Code Files

Code has its own natural structure that naive chunking destroys. A function split in half is useless. A class without its imports cannot be understood.

AST-Based Chunking

Parse the code into an **Abstract Syntax Tree** and split at natural boundaries: functions, classes, methods. Each logical unit becomes a chunk with its context preserved.

```
# When chunking a method, prepend class name and imports:

# From class DataProcessor (file: processor.py)
# Imports: pandas as pd, sklearn.model_selection.train_test_split

def clean(self):
    self.data = self.data.dropna()
    self.data = self.data.drop_duplicates()
    return self
```

- Use tree-sitter or language-specific AST parsers for accurate structure detection.
- Always include the class/module name and relevant imports with each code chunk.
- For documentation retrieval, pair each function chunk with its docstring.

5.3 Multimodal Content (Images, Charts, Diagrams)

Approach	Method	Best For	Tool Examples
Vision-to-Text	Use vision model to generate text description; embed the description	Charts, diagrams, screenshots	GPT-4o, Claude, Gemini
Multimodal Embeddings	Embed images directly into the same vector space as text	Photos, visual content	CLIP, Cohere Multimodal, Jina CLIP

Approach	Method	Best For	Tool Examples
Hybrid	Store both image and description; retrieve on text, pass image to multimodal LLM	Complex visuals needing both approaches	Custom pipeline

5.4 Conversational and Q&A Data

When your source data is conversations, chat logs, or FAQ-style content, standard chunking fails because it does not respect the question-answer or turn-based structure.

- **Keep Q&A pairs together:** Never split a question from its answer. Each pair is a natural chunk.
- **Long conversations:** Chunk by topic or thread, not by fixed size. A 50-message conversation covering 3 topics should produce 3 chunks.
- **Support tickets:** Include the ticket metadata (subject, category, resolution status) as chunk metadata for filtered retrieval.

6. Metadata Enrichment

A chunk without metadata is like a page torn from a book with no title, no author, no page number. **Metadata transforms chunks from isolated fragments into situated knowledge.**

6.1 Essential Metadata Fields

Field	Purpose	Example
source_document	Identify origin for citation and filtering	"2024_Annual_Report.pdf"
page_number	Enable page-level reference	47
section_hierarchy	Situate within document structure	"Ch 3 > Financial Performance > Revenue"
chunk_position	Know if context may be before/after	"middle" (3 of 7 in section)
document_date	Enable temporal filtering	"2024-03-15"
document_type	Enable type-based filtering	"annual_report"
content_type	Distinguish text vs table vs code	"table"
entities	Pre-extracted key entities	["Acme Corp", "Q3 2024"]

6.2 How Metadata Improves RAG

Filtered retrieval: "Find revenue information from the 2024 annual report" — filter by document name before semantic search. This dramatically reduces the search space and eliminates irrelevant matches from other documents.

Source attribution: Include metadata when passing chunks to the LLM. The model can then cite sources: "According to page 47 of the 2024 Annual Report..." This builds user trust and enables verification.

Deduplication: Metadata about chunk position helps identify and handle overlapping content from sliding window chunking, preventing redundant retrieval results.

7. Evaluating Chunking Quality

This is what separates hobbyist RAG from production RAG. Without evaluation, you are **guessing** whether your chunking strategy works. With evaluation, you have evidence.

7.1 Retrieval-Level Metrics

Metric	What It Measures	Formula Intuition
Recall@K	Of chunks containing the answer, what % appear in top-K?	Did we find the right chunks?
Precision@K	Of top-K retrieved chunks, what % are actually relevant?	Did we avoid irrelevant chunks?
MRR	How high is the first relevant chunk in results?	How quickly does the right answer appear?
nDCG@10	Quality of ranking, accounting for position of relevant results	Are the best chunks ranked highest?

7.2 End-to-End RAG Metrics

Metric	What It Measures	Why It Matters
Faithfulness	Is the LLM answer supported by retrieved chunks?	Detects hallucination
Answer Relevancy	Does the answer address the actual question?	Ensures usefulness
Context Relevancy	Are the retrieved chunks relevant to the question?	Validates retrieval quality
Answer Correctness	Does the answer match the ground truth?	The ultimate quality measure

7.3 Practical Evaluation Framework

Step 1: Create 50 to 100 question-answer pairs from your documents. For each question, note which document section contains the answer.

Step 2: Run your RAG pipeline with different chunking strategies, keeping all other variables constant (same embedding model, same LLM, same top-K).

Step 3: Measure whether the right chunks are retrieved (retrieval metrics) and whether the final answer is correct (end-to-end metrics).

Step 4: Use tools like RAGAS, DeepEval, or even manual spot-checking to automate this process.

> **The Most Underrated Evaluation Method**
>
> Simply LOOK at your chunks. Print out 20 random chunks and ask yourself: "If I read this chunk in isolation, does it make sense? Would it help me answer a question about this topic?" You will immediately spot problems that no metric can capture.

8. Common Failure Modes

Understanding failure modes is as important as understanding strategies. These are the patterns that break RAG pipelines in production.

Failure Mode	Symptom	Root Cause	Fix
The Cliffhanger	Chunk ends with "The solution is..." and next starts with "...to use caching"	Fixed-size split at wrong boundary	Use sentence-aware splitting or overlap
The Frankenchunk	Chunk contains end of one topic and start of another	Fixed-size glues unrelated sections	Structure-aware or semantic chunking
The Orphan Reference	"As shown in Table 3.2 above..." but Table 3.2 is in another chunk	Cross-reference lost at boundary	Contextual chunking or parent-child
The Table Massacre	Table split across 3 chunks; headers in one, data in others	No table detection	Special table handling (keep whole or serialize)
The Duplicate Flood	Top-5 returns 3 chunks that are 80% identical	Too much overlap	Reduce overlap or add dedup/reranking
The Lost Needle	Critical short sentence buried in a large chunk	Chunk too large, embedding diluted	Smaller chunks or proposition chunking

9. The Decision Framework

Choosing a chunking strategy should not be guesswork. Use this framework to make evidence-based decisions.

9.1 Start Simple, Upgrade with Evidence

Step 1 — Baseline: Recursive character splitting, 512 tokens, 50-token overlap. Measure retrieval quality on your evaluation set.

Step 2 — Diagnose: Look at retrieval failures. What pattern do they follow? Use the failure mode table above to identify the root cause.

Step 3 — Target: Apply the targeted fix for the specific failure mode you observe. Do not upgrade everything at once.

Step 4 — Measure: Measure the impact of the change on your evaluation set. If it helps, keep it. If not, revert.

9.2 Strategy Selection by Use Case

Use Case	Recommended Primary Strategy	Enhancement
General knowledge base	Recursive splitting (512 tokens, 50 overlap)	Metadata enrichment
Financial/legal documents	Structure-aware + contextual chunking	Parent-child + table handling
FAQ / Support content	Document structure (Q&A pairs as chunks)	Metadata tagging
Code repositories	AST-based chunking	Import/class context prepended
Research papers	Section-based splitting	Contextual chunking for cross-references
Mixed document types	Type-detection router + strategy per type	Full pipeline
Large-scale, cost-sensitive	Recursive splitting + late chunking	BM25 hybrid search
High-value, precision-critical	Contextual chunking + reranking	Proposition-based for key sections

9.3 Chunk Size Quick Reference

Chunk Size	Token Range	Best Query Type	Best Document Type
Small	128–256 tokens	Factoid questions ("What year?", "Who is?")	FAQs, contracts, definitions
Medium	256–512 tokens	Balanced queries ("Explain X", "How does Y?")	Reports, articles, documentation
Large	512–1024 tokens	Complex queries ("Compare X and Y", "Summarize")	Narratives, detailed analysis
Very Large	1024–2048 tokens	Summary/synthesis questions	Books, research papers (with parent-child)

10. Production Chunking Checklist

Before shipping your RAG pipeline to production, verify each of these items:

10.1 Ingestion Pipeline

- **Document type detection:** Route different file types (PDF, HTML, Markdown, code) to appropriate parsers.
- **Structure extraction:** Detect headings, tables, code blocks, images before chunking.
- **Table handling:** Tables are detected and processed with a dedicated strategy (kept whole, serialized, or summarized).
- **Chunk size validation:** No chunk exceeds the embedding model's token limit. No chunk is trivially small (under 50 tokens).
- **Overlap consistency:** If using overlap, verify it is consistent and does not create duplicate-heavy retrieval results.

10.2 Metadata

- **Source tracking:** Every chunk carries its source document ID, page number, and section.
- **Content type tagging:** Chunks are tagged as text, table, code, or image-description.
- **Temporal metadata:** Document dates are preserved for time-filtered retrieval.

10.3 Quality Assurance

- **Evaluation set:** You have at least 50 question-answer pairs for measuring retrieval quality.
- **Visual inspection:** You have manually reviewed at least 20 random chunks for coherence.
- **Failure mode analysis:** You have tested for each common failure mode and confirmed they do not occur.
- **A/B comparison:** You have compared at least two chunking strategies on your evaluation set.

10.4 Operational

- **Incremental updates:** Your pipeline can add/update/delete chunks without re-processing the entire corpus.
- **Cost monitoring:** You know the cost per document for chunking, embedding, and storage.
- **Deduplication:** Near-duplicate chunks from overlap or re-indexing are handled at retrieval time.

- **Logging:** Chunking decisions are logged for debugging retrieval failures.

11. Master Strategy Comparison

Use this table as a quick reference when choosing between strategies.

Strategy	Complexity	Cost	Quality	Best For
Fixed-Size	Very Low	Very Low	Low	Prototyping, baselines
Recursive Character	Low	Low	Medium-High	General purpose production
Sentence-Level	Low	Low	Medium	Clean text, NLP available
Document Structure	Medium	Low	High	Well-structured documents
Semantic (Embedding)	Medium	Medium	High	Topic-diverse documents
Proposition	High	High	Very High	Factoid retrieval, legal/medical
Agentic (LLM)	Very High	Very High	Highest	Small, high-value corpora
Parent-Child	Medium	Low	High	Any production system
Contextual (Anthropic)	Medium	Medium-High	Very High	Enterprise documents
Late Chunking (Jina)	Medium	Low	High	Large corpora, cost-sensitive

Final Recommendation

The best RAG systems do not use one chunking strategy. They use a pipeline that routes documents to different strategies based on content type, applies metadata enrichment, uses parent-child indexing for retrieval, and evaluates results continuously. Start simple, measure rigorously, and add complexity only when it demonstrably improves results.
